## **1. Introduction**

Rarotonga the capital of the Cook Islands is rapidly developing with tourism as one of the major income earners for the country. The health of the lagoon and reef is important for the welfare of the people. It is vital that the health of the lagoon is monitored and action is taken to protect the health of the lagoon, coral reef and the people that use it. Human activities contribute to the decreased water quality, for example farming of pigs, deforestation and farming crops close to streams. The water quality monitoring programme gives an evaluation of the state of the streams and the lagoon, and can be used to identify issues that need to be addressed.

In 2003, the Ministry of Marine Resources started to monitor the Rarotonga lagoon. Measurements included temperature, dissolved oxygen, pH, salinity, nutrients, chlorophyll *a*, suspended solids and bacterial contamination to measure long term changes in water quality of the lagoon and streams.

Temperature varies seasonally and influences the occurrence and growth of aquatic plants, and animals. The solubility of dissolved oxygen (DO) is regulated by temperature however other factors also affect DO including water flow. In the water, DO is either absorbed directly from the atmosphere or is produced by algae via photosynthesis and is removed by respiration and decomposition of organic matter. The recommended minimum for DO saturation is not less than 75% saturation for oceanic waters, embayments, open coastal waters and estuaries and not less than 80% for streams (Department of Health, Clean Water Branch Hawaii 1994). Salinity varies little in most marine environments and saltwater is normally between 34ppt and 36ppt in areas away from freshwater influences (Smith 2004). Moseley *et al.* (2004) in water quality guidelines developed for Pacific Countries suggest that pH should be between 8.0 and 8.4 in lagoon type environments. The Department of Health, Clean Water Branch Hawaii (1994) pH standard for open coastal waters is between 7.6 and 8.6 and can be as low as 7.0 in areas influenced by freshwater input.

Nutrients such as nitrate and phosphate which are naturally present in seawater are essential for the growth of phytoplankton and other algae which form the base of the food web. Elevated nutrients concentration can lead to an increase in algae and aquatic plants biomass which can have detrimental impacts on the coral reef health. The guidelines for nutrient concentrations for the protection of coral reef health are 14 $\mu\text{g/L}$

for dissolved inorganic nitrogen (DIN), which is made up of nitrate and ammonia ( $\text{NO}_3\text{-N} + \text{NH}_4\text{-N}$ ), and 2.6 $\mu\text{g/L}$  for dissolved reactive phosphorus (DRP) (Bell 1992). The ANZECC guideline values for streams or lowland rivers that are a cause for concern in Australia tropical areas based on measured values are 10 $\mu\text{g/L}$  for nitrate ( $\text{NO}_3\text{-N}$ ) and ammonia ( $\text{NH}_4\text{-N}$ ), and 4 $\mu\text{g/L}$  for DRP (ANZECC 2000).

Chlorophyll *a* and total suspended solids measure phytoplankton biomass, inorganic and organic particulate material in the water respectively. Elevated concentrations of both have been shown to impact negatively on coral reef health above concentration of 0.5 $\mu\text{g/L}$  and 4-5mg/L, respectively (Bell, 1992).

Increased inorganic and organic materials entering lagoons are often associated with increases in bacterial numbers which can potentially disease causing organisms. Enterococci bacteria are used to indicate the potential presence of human pathogens in marine and freshwater environment. Guidelines have been developed by the World Health Organisation (WHO) for contact recreation using Enterococci numbers (Table 1). This guideline is also used for freshwater samples to evaluate the bacterial water quality of the streams as they flow directly into the lagoon and are likely to impact the bacterial water quality of the lagoon.

**Table 1: WHO Standards for Bathing Water Quality (WHO 2001).**

Category	Indicator Counts	Microbiological Assessment
A.	$\leq 40$ Enterococci / 100ml	Suitable for swimming
B.	$\geq 41$ to $\leq 200$ Enterococci / 100ml	Suitable for swimming but requires surveillance
C.	$\geq 201$ to $\leq 500$ Enterococci /100ml	Not suitable for swimming, requires assessment
D.	$> 500$ Enterococci / 100ml	Not suitable for swimming, public warnings

This report is a Data Report summarising the findings of the water quality sampling program in 2009 and supports of the Water Quality Report Card. The Water Quality Report Card for Rarotonga 2010 is attached.

## **2. Methods**

### **2.1 Sampling**

All the water quality parameters were measured monthly for both lagoon and streams. In total there are 14 marine sites and 8 stream sites for Rarotonga (Figure 1 and Table 2 & 3). Water samples for Rarotonga were stored in the dark on ice and the samples were processed soon after sample collection.

## 2.2

## Rarotonga Marine and Stream Sampling site map

6	Betela	S21 14.739	W159 49.462
7	North Airport Drain	S21 12.214	W159 49.043
8	Avatiu	S21 12.342	W159 47.047

### 2.3 Physical Parameters

At each site temperature (°C), dissolved oxygen (DO), % saturation and concentration, pH, and salinity (‰) were measured using a YSI 556 Probe. The individual probes were calibrated before use in the field and measurements were made at each site at the time of sampling (Hall et al., 2007).

### 2.4 Nutrients

All water samples for nutrient analysis were filtered through a Whatman GF/F glass fibre filter into a 250ml acid washed plastic bottle. These samples were stored frozen until they were shipped on ice in chilly bins to NIWA for analysis. All nutrient

analysis were conducted using an Astoria Pacific auto-analyser 300 series with methods from the Astoria Pacific International Methods Manual (A 6/00). Nitrate were analysed by the cadmium column reduction method (Astoria 305-A177), DRP by the molybdenum blue method (Astoria 305-A204) and NH<sub>4</sub>-N by the indophenol blue method (Astoria 305-A026).

## **2.5 Chlorophyll *a* and Suspended Solids**

Samples for chlorophyll *a* and total suspended solids analysis of known volumes were filtered on to GF/F filters; chlorophyll *a* filters were frozen immediately and the suspended solid filters were dried in the oven after processing. The frozen filters for chlorophyll *a* were then analyzed later by acetone extraction and fluorometry (APHA 1998) in the MMR laboratory (Hall et al., 2007). Total suspended solids analysis followed Hall et al., (2007).

## **2.6 Bacteria**

Water samples collected for Enterococci were analysed in duplicate using membrane filtration method and placed on Enterococci agar. The volumes filtered differed depending on how clean the water was and on previous results. Enterococci plates were incubated at 37°C for 24 hours (Hall et al., 2007).

## **3. Results**

### **3.1 Missing Data**

#### **Lagoon**

There was only one missing data point in the sampling which was at East Airport Drain in the month of February. This was due to data not being stored into the YSI probe.

#### **Stream**

The pH data in November at all stream sites was omitted, due to the pH probe calibrations not being within specifications.

#### **4. Acknowledgments**

We thank Drs Julie Hall and Els Maas for both technical advice and editorial comments, Mike Crump and his team at NIWA for their technical support, and the staff of the Ministry of Marine Resources for editorial and sample collection. We are grateful to the National Environment Services for providing man power and transport during the sampling. Thanks also to the Cook Islands Meteorological Services for providing the weather and rainfall information. The Ministry of Marine Resources would also like to thank NZAid for all the funding support.
